## A320 & A330 Avionics

- **Avionics:** Aviation Electronics
	- Set of controls, sensors, computers, actuators
- 25+ ATA chapters
- Systems are mainly **independent**
- **ARINC 429 bus** 
	- **Unidirectional**, point to multi-point
	- 32bit at a time: 8bit label and 19bit data
		- Single value per label: speed, altitude…
	- Quite low speed: 100Kbps

**AIRBUS** 

## A380 & A350 Avionics

- Avionics Full DupleX AFDX
	- Deterministic Ethernet
	- Based on **Virtual Links**
		- Unidirectional, point to multi-point
	- Switches are enforcing Virtual Links
	- Bi-directional communication needs two VL
- **Integrated Modular Avionics** 
	- ARINC 653 API
	- Space and Time partitioning
	- Incremental certification
- **Open World**

### Security considerations

#### Security by obscurity **does not work**

- Confidentiality of specifications & designs is very hard to manage
- Think **insider attacks**
	- Wikileak
	- Edward Snowden…
- Think **leaks**
	- Shadow Brokers…

#### **Reverse engineering**

- 
- 
- It works well It is not so hard It is not necessarily expensive

- **Aircraft technologies**
- **Security bricks**
- **Security measures**
- **Aircraft security principles**

# **Cryptography Hash algorithms**

- Transform any file (or byte flow) to a unique fixed length value
	- SHA-1: 160 bit
	- SHA-2 256: 256 bit
- Properties
	- **One way** function: function which is infeasible to invert (except by brute force)
	- **Small change** to message should change digest a lot
	- Infeasible to find two different messages with **same digest**
	- **Deterministic**: same message always results same digest
	- **Quick** to compute
- Workhorse of cryptography

# **Cryptography Symmetric-key algorithms**

- Used for **encryption** confidentiality protection
- Algorithm examples: DES, 3DES, **AES**
- **Fast** algorithms, can be implemented in hardware
- Ciphertext is undistinguishable from **random text**
- Key length should be at least 128bit, preferably 256bit
- Exportation, importation, usage are **locally regulated**
- Message is only **as secure as the key**
- **Key distribution** is the issue

- Public key and private key are related
- It's not possible to find private key from public key
- What is encrypted with **public** key is decrypted only by **private** key
- What is encrypted with **private** key is decrypted only by **public** key
- Message is only as secure as the **private key**
- Ciphertext is undistinguishable from random text
- Algorithm examples: RSA, Elliptic Curves

©AIRBUS Operations S.A.S. All rights reserved. Confidential and proprietary document

# **Cryptography Asymmetric-key algorithms – proof of origin**

- Asymmetric-key algorithm are used for **many functions**
	- Encryption
	- **Authentication**
	- **Integrity**
- Exportation, importation, and usage are **locally regulated**
- How to distribute keys?
- Asymmetric algorithm are **slow**

#### 12 January 2019 Securing an Aircraft Information System

Function or device aimed at

- Looking at network packets
- **Deciding** if they can go on or have to be dropped

For IP communications

• Usually looks at level 3 and level 4 (IP addresses and TCP/UDP ports)

How to express the filtering policy?

- Not an easy job...
- Basic rule: **drop everything**, allow only what you need
- What can do an attacker of what you let go through?
	- No protection for what is allowed
	- Target is exposed without protection…

#### **The firewall is not the protection, the enforced filtering policy is**

![](_page_15_Picture_13.jpeg)

![](_page_15_Picture_15.jpeg)

### Application level gateway

Firewalls are filtering at layers 3 and 4

**IP addresses**, ports (≈ identification of applications), not looking at payload

Application level gateway aims at **filtering upper layers**

- It must **understand** protocols, **filter** application and protocol values
- Whatever accepted transmission must be **innocuous** for receiving application

Advantages

- Good security level, high confidence in security
- **The real application is protected**

**Consequences** 

• Costly to develop as **specific** to every application and protocol

**AIRB** 

### Virtual Private Network

Objective: communicate through an **untrusted network** as if you were on dedicated **private lines**

- Build communication channel with security properties (integrity, authenticity, confidentiality)
- Combining cryptographic primitives

![](_page_17_Figure_5.jpeg)

- Brings you confidence someone **external to the communication** will not read, modify or inject packets
- Does not protect you if attacker is **at the other side**…

![](_page_17_Picture_9.jpeg)

# Aircraft Protection Principles **Digital signature of software**

- Field Loadable Software (FLS)
	- *Field:* not in supplier's premises, can be done on aircraft
	- *Loadable:* can be changed or updated without specific tooling, without opening the box
	- *Software:* Executables, configuration and customization files, databases
- **Need to ensure** 
	- **Origin**: FLS had been produced by an authorized supplier
	- **Integrity**: FLS had not been modified since production by the supplier

![](_page_18_Figure_8.jpeg)

### Basic principles

**Asymmetry** 

 An **attacker** only has to find **one vulnerability** to exploit in order to start an attack, whereas a **defender** must guard against an attack on **any and every** service

#### **Security in depth**

- **Perfect protection is not possible**
- Objective is to slow down the attackers
- Discourage them by raising the technical problem

#### Global vision

- Security studies need a global vision of architecture and systems
- **It's the only way to prevent bypass**

#### Limit **attack surface**

#### **Do not imagine what attackers want to do, they will be more creative!**

## Environment and assumptions

Environment identifies **threat source** profile to be considered

- **Trust** environment has to be defined
- Without any trust, nothing is possible, impossible to protect from everything and everyone

Airline people are by default **trusted**

- **Flight crews**
- Cabin crews
- **Maintainers**

Nevertheless, by default the e-tools they use are **not trusted**

- Laptops, PCs (EFB, PMAT), tablets...
- USB sticks, SD cards...

Communications are by default **not trusted**

![](_page_21_Picture_14.jpeg)

![](_page_21_Picture_15.jpeg)

![](_page_21_Picture_16.jpeg)

![](_page_21_Picture_17.jpeg)

### Function protection

![](_page_22_Figure_1.jpeg)

- Functions **will be** attacked
	- Many entry points
- Functions are needed for **aircraft safety** and **operations**
	- Security is needed to ensure those functions will be available
- First reflex: **every function is to be protected**
	- Strength of protection depends on impact

![](_page_22_Picture_9.jpeg)

### Domain protection

![](_page_23_Figure_1.jpeg)

- Reduce cost by creating domains and **mutualizing** security barriers
	- **Layered** protection for most impacting functions
- Every security barrier is sufficient to face considered threat attack path
- **-** Layered protection gives time to correct vulnerabilities
	- If no layered protection  $\rightarrow$  disconnected the system after first vulnerability
- **Drawback: rebound attacks** 
	- Highest impact in the domain has to be taken into account

**AIRBUS** 

# Aircraft Protection Principles **Layered defense**

Aircraft security architecture must be based upon **layered protection** concept

![](_page_24_Picture_3.jpeg)

- Security boundary count is defined by aircraft safety impact of protected asset
	- ‒ *Strong* and *Very strong* safety impact requires at least **two barriers** between threat agents and impacted assets
- Security boundaries must be **designed** and **demonstrated** to have **no common vulnerabilities**
	- ‒ A single vulnerability must not endanger aircraft security
		- Different technologies: code, system architecture
		- Different COTS
		- Hardware based solution vs software based solution
- **At least one security barrier**

![](_page_24_Picture_13.jpeg)

**AIRBUS** 

# Aircraft Protection Principles **Additional properties**

• No bypass

![](_page_25_Picture_3.jpeg)

- **Fail secure** 
	- If a failure happens, stay secure!
	- Fail Secure vs Fail Safe

![](_page_25_Picture_7.jpeg)

# Aircraft Protection Principles **Work Impact**

- It's possible to protect something with
	- Technical measures
		- *Example:* firewall, VPN, physical device…
	- **Organisational measures**
		- Procedure, process
		- *Example:* ask maintainer to do a antivirus check on his USB stick before connecting it to the aircraft

#### **Fechnical measures** must be privileged at all times

- This avoid human errors or omissions
- This reduce burden for users

![](_page_26_Picture_12.jpeg)

## Threats to counter **Food for thought for protection**

- What can be done with what you functionally allow
	- ‒ If you can ask nicely to perform a bad action, why bother doing something else?
- Attacks can be on infrastructure and software too
	- ‒ Buffer overflow attacks and others…
- Denial of Services
	- ‒ Resource exhaustion
	- ‒ Flooding
- Attacks on communication means
	- ‒ Spoofing
	- ‒ Man in the Middle
	- ‒ Jamming
- Degraded & backup modes
	- ‒ They are simpler and not necessarily protected

![](_page_27_Picture_14.jpeg)

- [Monitoring & administration systems](https://www.google.fr/url?sa=i&rct=j&q=&esrc=s&source=images&cd=&cad=rja&uact=8&ved=0ahUKEwjg6Lf59p7SAhVCfxoKHU-XBK4QjRwIBw&url=https://virusremovalexpert.wordpress.com/2010/11/02/eight-threats-your-anti-virus-will-not-stop/&psig=AFQjCNHQQhdho2To6zqnr-pn8KWU7eMyqg&ust=1487680468397720)
	- ‒ They access all systems
	- They are a central point of attack
	- ‒ They could allow easy remote control
	- ‒ Front face plugs can be a threat too
- Data loading
	- ‒ If the attacker can change the software used, why protect...?
	- ‒ It's a central point of attack

**AIRBU** 

### Trade-offs & decisions

#### **Technical feasibility, cost, weight & volume, performance**

- Cyber Security **effectiveness**
- Capacity to **demonstrate** to Airworthiness Authorities
- **Industrial constraints**
- **Evolution possibilities** (build modular architecture, use bricks)
- **Infrastructure capacity** to host the security measure
- There is more than one solution!
- Challenge proposed solution with regard to original objective
- Risk management
	- ‒ Risk acceptance

![](_page_28_Picture_11.jpeg)

![](_page_28_Picture_13.jpeg)

# General IT security *vs* Aircraft Security **Where are the particular difficulties?**

- No on-board security administrator
	- Monitoring cannot be done in real time by humans
- Cycles are different
	- Update cycles cannot be the same
	- Development time are longer
	- Configuration Management is requested by operations and imposes additional work
	- Systems are designed for the lifetime of an aircraft  $-25$  to 50 years
- **Diversity & multiplicity of interconnected systems** 
	- E.g. ATM systems are different from one country to another during the same flight
- **Certification** 
	- Certification process is long and costly
	- Need to convince Authorities
- **Taking into account existing architectures**
- **Consequences are usually bigger** 
	- Safety
	- Liability
- Communications
	- Cost
	- Roaming
	- Intermittence

![](_page_29_Picture_24.jpeg)

### Security engineering

- **Requirement Based Engineering**
- Writing security specification is a nightmare
	- This is not enough!

![](_page_30_Picture_5.jpeg)

#### $\rightarrow$  Need for other activities

![](_page_30_Picture_8.jpeg)

![](_page_31_Picture_0.jpeg)
